## THEORY:

Circuit that takes the logical decision and the process are called logic gates. Each gate has one or more input and only one output.

OR, AND and NOT are basic gates. NAND, NOR and X-OR are known as universal gates. Basic gates form these gates.

## AND GATE:

The AND gate performs a logical multiplication commonly known as AND function. The output is high when both the inputs are high. The output is low level when any one of the inputs is low.

## OR GATE:

The OR gate performs a logical addition commonly known as OR function. The output is high when any one of the inputs is high. The output is low level when both the inputs are low.

## NOT GATE:

The NOT gate is called an inverter. The output is high when the input is low. The output is low when the input is high.

## NAND GATE:

The NAND gate is a contraction of AND-NOT. The output is high when both inputs are low and any one of the input is low. The output is low level when both inputs are high.

## NOR GATE:

The NOR gate is a contraction of OR-NOT. The output is high when both inputs are low. The output is low when one or both inputs are high.

## X-OR GATE:

The output is high when any one of the inputs is high. The output is low when both the inputs are low and both the inputs are high.

## PROCEDURE:

(i) Connections are given as per circuit diagram.
(ii) Logical inputs are given as per circuit diagram.
(iii) Observe the output and verify the truth table.

## THEORY:

## HALF ADDER:

A half adder has two inputs for the two bits to be added and two outputs one from the sum ' $S$ ' and other from the carry ' $c$ ' into the higher adder position. Above circuit is called as a carry signal from the addition of the less significant bits sum from the X-OR Gate the carry out from the AND gate.

## FULL ADDER:

A full adder is a combinational circuit that forms the arithmetic sum of input; it consists of three inputs and two outputs. A full adder is useful to add three bits at a time but a half adder cannot do so. In full adder sum output will be taken from X-OR Gate, carry output will be taken from OR Gate.

## THEORY:

## HALF SUBTRACTOR:

The half subtractor is constructed using X-OR and AND Gate. The half subtractor has two input and two outputs. The outputs are difference and borrow. The difference can be applied using X-OR Gate, borrow output can be implemented using an AND Gate and an inverter.

## FULL SUBTRACTOR:

The full subtractor is a combination of X-OR, AND, OR, NOT Gates. In a full subtractor the logic circuit should have three inputs and two outputs. The two half subtractor put together gives a full subtractor .The first half subtractor will be C and A B. The output will be difference output of full subtractor. The expression AB assembles the borrow output of the half subtractor and the second term is the inverted difference output of first X-OR.

## THEORY:

The availability of large variety of codes for the same discrete elements of information results in the use of different codes by different systems. A conversion circuit must be inserted between the two systems if each uses different codes for same information. Thus, code converter is a circuit that makes the two systems compatible even though each uses different binary code.

A code converter is a circuit that makes the two systems compatible even though each uses a different binary code. To convert from binary code to Excess-3 code, the input lines must supply the bit combination of elements as specified by code and the output lines generate the corresponding bit combination of code. Each one of the four maps represents one of the four outputs of the circuit as a function of the four input variables.

A two-level logic diagram may be obtained directly from the Boolean expressions derived by the maps. These are various other possibilities for a logic diagram that implements this circuit.

| 5. | PATCH CORDS | - | As per requirement |

## THEORY:

The Digital Comparator is another very useful combinational logic circuit used to compare the value of two binary digits. A magnitude digital Comparator is a combinational circuit that compares two digital or binary numbers in order to find out whether one binary number is equal, less than or greater than the other binary number. We logically design a circuit for which we will have two inputs one for A and another for B and have three output terminals, one for $\mathrm{A}>\mathrm{B}$ condition, one for $\mathrm{A}=\mathrm{B}$ condition and one for $\mathrm{A}<\mathrm{B}$ condition.

A comparator used to compare two bits is called a single bit comparator. It consists of two inputs each for two single-bit numbers and three outputs to generate less than, equal to and greater than between two binary numbers

Digital comparators actually use Exclusive-NOR gates within their design for comparing their respective pairs of bits. When we are comparing two binary or BCD values or variables against each other, we are comparing the "magnitude" of these values, a logic " 0 " against a logic " 1 " which is where the term Magnitude Comparator comes from.

## THEORY:

## MULTIPLEXER:

Multiplexer means transmitting a large number of information units over a smaller number of channels or lines. A digital multiplexer is a combinational circuit that selects binary information from one of many input lines and directs it to a single output line. The selection of a particular input line is controlled by a set of selection lines. Normally there are $2^{n}$ input line and $n$ selection lines whose bit combination determine which input is selected.

## DEMULTIPLEXER:

The function of Demultiplexer is in contrast to multiplexer function. It takes information from one line and distributes it to a given number of output lines. For this reason, the demultiplexer is also known as a data distributor. Decoder can also be used as demultiplexer. In the 1:4 demultiplexer circuit, the data input line goes to all of the AND gates. The data select lines enable only one gate at a time and the data on the data input line will pass through the selected gate to the associated data output line.

## THEORY:

## ENCODER:

An encoder is a digital circuit that perform inverse operation of a decoder. An encoder has $2^{n}$ input lines and $n$ output lines. In encoder the output lines generates the binary code corresponding to the input value. In octal to binary encoder it has eight inputs, one for each octal digit and three output that generate the corresponding binary code. In encoder it is assumed that only one input has a value of one at any given time otherwise the circuit is meaningless. It has an ambiguila that when all inputs are zero the outputs are zero. The zero outputs can also be generated when $\mathrm{D} 0=1$.

## DECODER:

A decoder is a multiple input multiple output logic circuit which converts coded input into coded output where input and output codes are different. The input code generally has fewer bits than the output code. Each input code word produces a different output code word i.e there is one to one mapping can be expressed in truth table. In the block diagram of decoder circuit the encoded information is present as n input producing $2^{\mathrm{n}}$ possible outputs. $2^{\mathrm{n}}$ output values are from 0 through out $2^{\mathrm{n}}-1$.

## THEORY:

A counter is a register capable of counting number of clock pulse arriving at its clock input. Counter represents the number of clock pulses arrived. A specified sequence of states appears as counter output. This is the main difference between a register and a counter. In synchronous common clock is given to all flip flop and in asynchronous first flip flop is clocked by external pulse and then each successive flip flop is clocked by Q or Q output of previous stage. Because of inherent propagation delay time all flip flops are not activated at same time which results in asynchronous operation.

## Experiment No : 09 DESIGN AND IMPLEMENTATION OF SHIFT REGISTER

AIM: To design and implement Serial in serial out, Serial in parallel out, Parallel in serial out and Parallel in parallel out shift register.

## APPARATUS REQUIRED:

| Sl. No. | COMPONENT | SPECIFICATION | QTY. |
| :---: | :--- | :---: | :---: |

| 2. | OR GATE | IC 7432 | 1 |
| 3. | IC TRAINER KIT | - | 1 |
| 4. | PATCH CORDS | - | 35 |

## THEORY:

A register is capable of shifting its binary information in one or both directions is known as shift register. The logical configuration of shift register consist of a D-Flip flop cascaded with output of one flip flop connected to input of next flip flop. All flip flops receive common clock pulses which causes the shift in the output of the flip flop. The simplest possible shift register is one that uses only flip flop.

ADDITION OF 8-BIT NUMBER
AIM: To add two 8 bit numbers stored at consecutive memory locations.

## ALGORITHM:

1. Initialize memory pointer to data location.
2. Get the first number from memory in accumulator.
3. Get the second number and add it to the accumulator.
4. Store the answer at another memory location.

## RESULT:

Thus the 8 bit numbers stored at $4500 \& 4501$ are added and the result stored at $4502 \& 4503$.

## Experiment No : 11 SUBTRACTION OF 8-BIT NUMBER

AIM: To Subtract two 8 bit numbers stored at consecutive memory locations.

## ALGORITHM:

1. Initialize memory pointer to data location.
2. Get the first number from memory in accumulator.
3. Get the second number and subtract from the accumulator.
4. If the result yields a borrow, the content of the acc. is complemented and 01 H is added to it ( 2 's complement). A register is cleared and the content of that reg. is incremented in case there is a borrow. If there is no borrow the content of the acc. is directly taken as the result.
5. Store the answer at next memory location.

## RESULT:

Thus the 8 bit numbers stored at $4500 \& 4501$ are subtracted and the result stored at $4502 \& 4503$.

## Experiment No : 12 LARGEST ELEMENT IN AN ARRAY

AIM: To find the largest element in an array.

## ALGORITHM:

1. Place all the elements of an array in the consecutive memory locations.
2. Fetch the first element from the memory location and load it in the accumulator.
3. Initialize a counter (register) with the total number of elements in an array.
4. Decrement the counter by 1 .
5. Increment the memory pointer to point to the next element.
6. Compare the accumulator content with the memory content (next element).
7. If the accumulator content is smaller, then move the memory content (largest element) to the accumulator. Else continue.
8. Decrement the counter by 1 .
9. Repeat steps 5 to 8 until the counter reaches zero
10. Store the result (accumulator content) in the specified memory location.

## RESULT:

Thus the largest number in the given array is found out.
